This document summarizes clinical studies conducted with the Tübingen Hip Flexion Splint. The included studies were identified by a literature search made on PubMed and within the journals Orthopädie-Technik, Medizinisch Orthopädische Technik, Neurologie & Rehabilitation and Journal of Pediatric Orthopaedics.

## 1 Overview table

The summaries are organized in three levels depending on the detail of information. The overview table (Level 1) lists all the relevant publications dealing with a particular product (topic) as well as researched categories (e.g. gait analysis, clinical effects, satisfaction, etc). By clicking on underlined categories, a summary of all the literature dealing with that category will open (Level 2).

For those interested to learn more about individual studies, a summary of the study can be obtained by clicking on the relevant reference (Level 3).

![Diagram showing 92% successful treatment and 8% no successful treatment](image)

**Clinical Relevance**

"Developmental dysplasia of the hip (DDH) includes a series of anomalous conditions where hip joint dislocation, instability, or malalignment is present (Pavone et al. 2015)." Making reference to Ziegler et al. (2008) the incidence of DDH in Central Europe is between 2% and 4% with a luxation rate ranging from 0.5% to 1%. DDH is mainly diagnosed by ultrasonography (Pavone et al. 2015). The classification system of Graf (2007) allows the classification of hip types according to the severity of DDH.

The Tübingen hip flexion splint, described by Bernau (1990), aims at achieving and maintaining reduction of the hip by providing abduction and flexion. An advantage of the Tübingen hip flexion splint is that the child is able to move the knee and ankle joints while the splint is applied. Important factors influencing treatment success are early diagnosis and early treatment (Atalar et al. 2014).

**Summary**

Three studies evaluated the effectiveness of the Tübingen hip flexion splint:

92.28-98% of the observed hips were successfully treated with the Tübingen hip flexion splint (Atalar et al. 2014, Pavone et al. 2015, Seidl et al. 2012).

Complications (in form of avascular necrosis) due to treatment were only observed in 0.55% of hips (Pavone et al. 2015).

Treatment of Developmental Dysplasia of Hip with Tübingen Hip Flexion Splint

### Products

Tübingen Hip Flexion Splint

### Major Findings

With Tübingen hip flexion splint:

➔ 92% of the treated dysplastic, unstable or dislocated hips were successfully converted into type 1 hips with an α-angle of >64° in the splint

➔ In 0.55% of hips complications were reported

➔ No statistic significant relationship between duration of therapy and time when treatment was started if treatment was started early within the first week of life

### Amount of successful treatment of hip dysplasia with the Tübingen hip flexion splint

![Pie chart showing 92% successful treatment and 8% no successful treatment]

### Population

Subjects: 351 children with 544 hips requiring treatment
- 248 female, 103 male

Inclusion criteria: hip dysplasia

Hip dysplasia:
- 158 unilateral, 193 bilateral
- Type (according to Graf):
  - IIb (355), IIc-IIIa (127), III (51), IV (11)
Study Design

Retrospective study:

![Flowchart]

After fitting with the Tübingen hip flexion splint hip maturity was evaluated every 3 to 4 weeks until hip maturity was reached. Afterwards the weaning period started within which the harness was only dressed for night time (14 hours a day) for a period of 4 to 10 weeks. Yearly follow-up evaluations were performed until skeletal maturity.

Author's Conclusion

“In conclusion, Tubingen harness, derived from Pavlik harness, has undergone a positive development and improvement and represents the treatment of choice in the DDH. This brace has shown a high success rate with a reduction in the incidence of short-term complications and developmental disorders of hip joint. Important factors are represented by an early age of beginning of the treatment, by its duration and by close ultrasonographic monitoring to evaluate the evolution of the condition and the possible occurrence of complications. Surgical treatment remains the last choice for patients in whom conservative treatment has failed.” (Pavone et al. 2015)
With Tübingen hip flexion splint:

• **93% of the examined hips were successfully treated**
  (Graf type 1 and no acetabular dysplasia)

**Amount of successful treatment of hip dysplasia with the Tübingen hip flexion splint**

![Diagram showing 93% and 7% success rates]

**Population**

**Subjects:** 49 children with 60 hips requiring treatment
45 female, 4 male

**Inclusion criteria:** diagnosis of hip dysplasia

**Study Design**

Retrospective study:

- Diagnosis of hip dysplasia
- Treatment with Tübingen hip flexion splint for 3 to 4 weeks
- Evaluation of hip maturity
- Continuation of treatment
- Evaluation of hip maturity
- Weaning period
- Evaluation of hip maturity

Hip maturity was assessed after 3 to 4 weeks of wearing the orthosis. If an improvement in hip maturity was observed, treatment was continued with regular follow-ups. After acetabular maturation, the weaning period was started where the splint was removed for a specific (growing) period of time per day.

### Author's Conclusion

“The Tübingen splint provides abduction, but due to its different design it offers the advantages of preventing hip adduction and leaving the knee and ankle joints free. Our findings suggest that in infants with DDH, the Tübingen hip flexion splint is an effective form of treatment.” (Atalar et al. 2014)
Reduction of unstable and dislocated hips applying the Tübingen hip flexion splint

Die Tübinger Hüftbeugeschiene als Repositionsorthese?

Der Orthopäde 2012; 41: 195-199.

**Products**

Tübingen Hip Flexion Splint

**Major Findings**

With Tübingen hip flexion splint:

- **98% of hips were successfully treated (successfully converted into type I hips with an \(\alpha\)-angle of more than 64° in the splint)**
  
  Mean time for achieving an \(\alpha\)-angle \(\geq 64°\): 51.6 ± 18.9 days

- **2% of hips (type IV hip) could not be reduced**

- **No significant relationship between duration of therapy and time when treatment was started if start of treatment was within the first week of life**

- **No correlation between duration of therapy and initial hip type**

Amount of successful treatment of hip dysplasia with the Tübingen hip flexion splint

- 98% successful treatment
- 2% no successful treatment

**Population**

Subjects: 42 newborns with 50 hips requiring treatment

35 female, 7 male

Hip dysplasia: 34 unilateral, 8 bilateral

Type (according to Graf):

IIc unstable (6), D (33), IIIa (10), IV (1)
### Study Design

Prospective cohort study:

- Postnatal ultrasound / diagnosis
- Fitting with Tübingen hip flexion splint
- Clinical and sonographic follow-ups max. 3 weeks apart
- End of treatment

### Author's Conclusion

“When recognized within the first week of life dysplastic unstable hips (type IIc unstable according to the classification of Graf) and dislocated hips with a cranially dislocated cartilage roof (types D and III according to the classification of Graf) can be successfully treated with the Tübingen hip flexion splint provided that the parents show good compliance concerning the treatment regimen.” (Seidl et al. 2012)
