Uncertainty adjustment

The uncertainty value per project is calculated by dividing the confidence interval value for individual project by the change in above ground biomass within one measuring period (Equation 7). Equation 10 is applied only to the plots with positive change in AGB within a measuring period. At least 500 plots (n) with positive change in AGB are required per project in order to calculate the uncertainty value. If the number of plots with positive change in AGB within a project is below 500, the uncertainty adjustment factor cannot be applied. Therefore, a default value of 0 uncertainty adjustment will be applied until the project reaches the desired number of plots. If adjustments need to be applied thereafter, the value will be applied on a project level in the following measuring periods.

$$U = \frac{CI_{\sigma}}{AGB_{\Delta x}}$$

Equation 7

Where:

- U = Project uncertainty for positive change of AGB within a measuring period
- CI_{σ} = Half-width of a 90% confidence interval
- $AGB_{\Delta x}$ = The mean positive change in aboveground biomass for n number of plots

Confidence interval (CI) is calculated following Equation 8.

$$CI_{\sigma} = 1.645 \frac{\sigma}{\sqrt{n}}$$

Equation 8

Where:

- σ = Standard deviation of positive change in AGB within a measuring period.
- CI_{σ} = Half-width of a 90% confidence interval
- n = refers to number of plots.

For U values greater than 50%, the following formula is applied in order to determine the appropriate uncertainty adjustment factor (U_{adjf}) - equation 9.

$$U_{adjf} = 0.25 * (U - 0.5)$$

Equation 9
