Alzheimer’s disease may progress slowly over 10-20 years.1,2 During this time, people living with Alzheimer’s disease experience a continuum of symptoms, ranging from non-symptomatic preclinical Alzheimer’s disease to severe dementia.3 As an individual’s disease and symptoms progress, Alzheimer’s disease increasingly impacts their daily life, routine, and independence.1 Collectively, people with mild cognitive impairment or mild dementia, when due to Alzheimer’s disease, can be described as individuals with early symptomatic Alzheimer’s disease.

Early symptoms of Alzheimer’s disease could appear as:4

- worsening memory loss
- difficulty completing familiar tasks
- confusion with time or place
- new problems with words in speaking or writing
- misplacing things and losing the ability to retrace steps

Scientific advancements in biomarker-driven Alzheimer’s disease diagnostics, such as amyloid positron emission tomography (PET) imaging of the brain, are being combined with other clinical assessments to facilitate timelier confirmatory diagnoses.5

Amyloid PET scans, cerebrospinal fluid (CSF) tests, and blood-based tests detect biomarkers such as amyloid.8 While amyloid naturally occurs, in some individuals amyloid can build up into plaques. This buildup of amyloid plaques may be associated with memory or thinking problems.2

Facilitating timely, affordable access to necessary clinical assessments and diagnostics is essential for improving the timelines of Alzheimer’s disease detection and diagnosis.2,8

The Need for Timely Detection and Diagnosis

Concerns about cognitive health and memory or thinking issues can be intimidating to confront, but early symptomatic Alzheimer’s disease should not be dismissed as normal aging.8 Timely detection and accurate diagnosis are essential.

Timely diagnosis can help identify or eliminate Alzheimer’s disease as the cause of a person’s memory and thinking issues.9 Ultimately, receiving an Alzheimer’s disease diagnosis earlier in the disease progression affords patients, loved ones, and providers more time to make personal and medical decisions.2,8
