

# **Greater Manchester's Clean Air Plan to tackle Nitrogen Dioxide Exceedances at the Roadside: Option for Consultation**

## **Local Plan Air Quality Modelling Report (AQ3)**

Salford City Council

**Warning:** Printed copies of this document are uncontrolled

<b>Version Status:</b>	APPROVED	<b>Prepared by:</b>	Transport for Greater Manchester on behalf of the 10 Local Authorities of Greater Manchester
<b>Authorised by:</b> <b>Date:</b>	Ian Palmer 31 <sup>ST</sup> January 2020		

## **COVID-19 Pandemic Statement**

This work has not considered the impact of the COVID-19 pandemic. Whilst we are continuing, where possible, to develop the Greater Manchester Clean Air Plan, the pandemic has already had an impact on our ability to keep to the timescales previously indicated and there may be further impacts on timescales as the impact of the pandemic becomes clearer.

We are also mindful of the significant changes that could result from these exceptional times. We know that the transport sector has already been impacted by the pandemic, and government policies to stem its spread. The sector's ability to recover from revenue loss, whilst also being expected to respond to pre-pandemic clean air policy priorities by upgrading to a cleaner fleet, will clearly require further thought and consideration.

The groups most affected by our Clean Air Plan may require different levels of financial assistance than we had anticipated at the time of writing our previous submission to Government.

More broadly, we anticipate that there may be wider traffic and economic impacts that could significantly change the assumptions that sit behind our plans. We have begun to consider the impacts, and have committed to updating the government as the picture becomes clearer over time.

We remain committed to cleaning up Greater Manchester's air. However, given the extraordinary circumstances that will remain for some time, this piece of work remains unfinished until the impact of the COVID-19 pandemic has been fully considered by the Greater Manchester Authorities.

	Appendix B – Model Results .....	51
	Appendix C – Sensitivity Testing.....	82

## 1 Introduction

- 1.1.1 The Greater Manchester Urban Area Zone is one of 37 zones across the UK where, based on the Department for the Environment, Food and Rural Affairs (Defra) modelling for 2015, annual mean nitrogen dioxide ( $\text{NO}_2$ ) concentrations exceeded the statutory Limit Values set by the European Union (EU) based on the World Health Organisation's air quality guidelines. These EU Limit Values were directly transposed into UK law as part of the Air Quality Standards Regulation 2010, and subsequently the Air Quality (Amendment of Domestic Regulations) (EU Exit) Regulations 2019. Of the ten Local Authorities within Greater Manchester (GM), seven are predicted to include road links which exceed the EU limits beyond 2020.
- 1.1.2 In order to address these exceedances, Defra and the Department for Transport (DfT) has set out an approach to introduce targeted local measures to bring  $\text{NO}_2$  concentrations within legal limits, in their Clean Air Zone Framework and the National Plan. The Joint Air Quality Unit (JAQU), comprising teams from Defra and the DfT, has been set up specifically to deliver the National Plan to improve air quality and comply with the EU Limit Value (EU LV) and the equivalent UK Air Quality Objective (AQO). The JAQU guidance documents set out the assessment process and typical measures that an authority should consider to deliver compliance with the  $\text{NO}_2$  annual mean AQO of  $40 \mu\text{g}/\text{m}^3$ .
- 1.1.3 Many local authorities across the UK (including eight within GM) have been instructed by JAQU to undertake detailed feasibility studies and develop plans for the implementation of appropriate measures to deliver compliance with the AQO in the 'shortest possible time'. According to the Supreme Court ruling the feasibility study must consider all options which are 'technically feasible' to be delivered in the shortest possible time and at least as quickly as a charge-based Clean Air Zone (CAZ) could. Local authorities need to consider a range of measures, including a charge-based CAZ as required by Government and set out in the JAQU guidance. The charge-based CAZ scenario is to be used as the reference case in terms of timescales and cost, against which other alternative measures are considered. It is the Government's preference that a charge-based CAZ is only implemented if other measures cannot deliver compliance in similar timescales while providing the same value for money.
- 1.1.4 TfGM is acting on behalf of the Greater Manchester Combined Authority (GMCA) and the ten Greater Manchester Local Authorities to undertake the feasibility study and develop the Greater Manchester Clean Air Plan (GM CAP) to meet the air quality challenge.

- 1.1.5 As required by JAQU, this ‘AQ3’ document provides the air quality results and discussion of the GM CAP options that have been assessed. Specifically, this document sets out the results of the proposed option for consultation. A summary of the methodology is set out in the Local Plan Air Quality Modelling Tracking Table (AQ1) and Local Plan Air Quality Modelling Methodology Report (AQ2), which underpins any air quality modelling for the baseline (2016) and the Do-Minimum (2021, 2023 and 2025) scenarios.
- 1.1.6 Details of the approach to model verification are provided in Appendix A. The full set of air quality modelling results are tabulated in Appendix B. Details of the Sensitivity Testing are reported in Appendix C.
- 1.1.7 Further information on the options development and the transport modelling are available in the Outline Business Case and supporting documents, and the equivalent transport modelling technical documentation (T1/T2/T3/T4), and in the version of AQ3 published at OBC.

## **2 Methodology Overview**

- 2.1 Based on Government guidance, the following local evidence was used to understand likely NO<sub>2</sub> concentrations in Greater Manchester beyond 2020:
  - Detailed Baseline Year (2016) and Future Years (2021, 2023 and 2025) transport model (actual and future demand on the road network);
  - Local vehicle fleet profiles (e.g. ages and types of vehicle) using Automatic Number Plate Recognition (ANPR) data;
  - Vehicle fleet licensing data for bus and taxi fleets;
  - Local background concentrations of NOx and NO<sub>2</sub>;
  - More detailed road network and junction data (e.g. alignment and width);
  - Representation of “air pollution” canyons (e.g. tall buildings);
  - Local air quality monitoring data from across Greater Manchester, which is described in AQ2 and presented in Figure 1; and
  - Confirmed future changes to the road network, and expected regional traffic growth and changes to the traffic fleet.
- 2.2 This local modelling was necessary to provide a more comprehensive understanding of the air quality across the entirety of Greater Manchester. The local modelling identified a larger number of locations which are expected to exceed the EU Limit Value, and higher concentrations of NO<sub>2</sub> in specific locations. This meant that all ten local authorities contained locations expected to be in exceedance of EU Limit Value for NO<sub>2</sub> after 2020. This reflected the fact that the local modelling used more detailed sources of data and more refined analytical tools. This resulted in three fundamental differences compared to the national modelling:

- The vehicle fleet in Greater Manchester is older and more polluting than assumed in the national model;
- In some areas vehicles are moving more slowly than assumed in the national model; and
- The background concentrations from non-road vehicle emissions sources (for example, electricity production, industry, local heating etc.) is higher than expected and needed to be uplifted.

- 2.2.1 Dispersion modelling of air quality produces outputs at specific coordinate points which predict a concentration of NO<sub>2</sub>. However, JAQU specify that these points should represent a worst case location along a more general length of road, aimed at correlating with the relatively long sections of road links defined for use in the Government's more coarse Pollution Climate Mapping (PCM) model. This guidance also states to exclude locations close to junctions. Presenting point data provides more specific and spatially detailed information about air quality, as it allows an understanding of how concentrations of NO<sub>2</sub> vary at different locations along the road.
- 2.2.2 In order to compare local modelling results with the PCM model outputs, receptors were automatically generated using a GIS script at 4m from the modelled road edge at 2m elevation, at locations >25m from junctions (as per the parameters set out in the JAQU Evidence Guidance), on both sides of the road. These receptors were generated for every road link in the GM Saturn model. The GM Saturn model is more spatially detailed than the PCM model, and each PCM link can extend over many Saturn links. The maximum locally modelled receptor concentration adjacent to each PCM road link was selected for comparison with the PCM model prediction.
- 2.2.3 Consistent with the Outline Business Case (OBC), this version of reporting presents concentration and emissions information on the basis of point data, but the AQ3 document will also align these to key PCM links.
- 2.2.4 A range of sensitivity tests will be undertaken for the Full Business Case (FBC) submission, based on the JAQU guidance. These will be reported in Appendix C.

#### **Updates to the Modelling Process post-OBC**

- 2.2.5 Since the production of the modelling for the OBC, there have been a number of updates to best practice tools and datasets. These have led to updates to the modelling of projected future year traffic and vehicle emissions.
- 2.2.6 There have been no updates to the 2016 Base model applied.

## **Do Minimum 2021, 2023 & 2025**

- 2.2.7 Since the OBC modelling, there have been a number of updates to the future year Do Minimum modelling process. During discussions with JAQU it was confirmed that these alterations did not constitute a change to the Target Determination process, but were appropriate technical refinements based on more up to date datasets.
- 2.2.8 These updates are:
- Update of Bus Routes and services and fleets. This has had two effects. Firstly, the OBC used a 2015/16 operational dataset which was correct for the Base Year model verification, and the fleet was then projected to the future years of 2021/2023/2025. The current modelling update has used the most recently available 2019 bus dataset and projected forward based on the OBC fleet-rollover method. This has resulted in an older future year bus fleet than was projected in the OBC, because bus operators have not invested in newer bus fleet as much since 2016 as in preceding years, which has the effect of increasing future emissions on a per vehicle basis. Secondly, overall bus mileage across GM has reduced by approx. 11% compared with the OBC assumptions, as operators have stopped running some less profitable routes.
  - These factors in combination will have the overall effect of increasing the Do Minimum bus emissions compared with the OBC, because the impact of the older fleet is more significant than the reduced mileage. However, in Do Something scenarios, a 100% Euro VI fleet was assumed in the OBC and this modelling version. Therefore, the reduced mileage will be the only variant, and bus emissions will be reduced compared with the OBC.
  - Updates to the Emission Factor Toolkit (from v8.0 to v9.1a) and associated NOx-to-NO<sub>2</sub> tool. This has primarily affected the split of petrol and diesel cars, increasing the petrol and EV/hybrid fleet in line with more recent sales trends. Overall this has reduced NOx emissions compared with OBC by approx. 2%, however this varies depending on the vehicle mix on a given road. Furthermore, because petrol cars have lower primary-NO<sub>2</sub> than diesel cars, there is a secondary effect which further reduces the final NO<sub>2</sub> concentrations.
  - Growth of LGVs. The demand matrices had not been correctly projected forwards in the OBC modelling. This correction has increased LGV emissions by approx. 1%.
  - Reduced number of modelled output points. In order to speed up model processing, only those sites that were predicted to be >38 ug/m<sup>3</sup> in the OBC Do Minimum 2021 have been calculated herein. This reduces the number of output points reported from ~17,000 to ~2,500.

### **3 Without Scheme Results**

#### **Model Results and PCM Exceedance Link Comparison: Do Minimum 2021**

- 3.1.1 As part of the Target Determination process, the local modelling is compared against the national PCM model (2015 base, as referenced in the Direction). The results for these locations, where the PCM model has predicted exceedances leading to authorities being included in the National Plan, are presented in Table 1.
- 3.1.2 The results of the modelling are subsequently presented for each local authority separately. This discussion reports the total number of assessed modelled locations in exceedance by road link. The maximum result for each PCM link is then also tabulated and along with information on background concentrations and vehicle type source apportionment.

**Table 1: Model results and PCM Links leading to Districts being named in the National Plan – Do Minimum 2021**

Census ID	Road Name	Local authority	PCM NO <sub>2</sub> conc. ( $\mu\text{g}/\text{m}^3$ )	Local Model Results ( $\mu\text{g}/\text{m}^3$ )					Local Model : PCM
				Total NO <sub>2</sub>	BG <sup>1</sup> NOx	BG NO <sub>2</sub>	Road NOx	Road NO <sub>2</sub>	
7431	A666	Bolton	40.6	44.0	26.5	18.4	53.7	25.6	108%
38354	A58	Bury	41.5	52.8	23.0	16.3	88.8	36.5	127%
37809	A5103	Manchester	41.2	38.8	16.8	12.3	54.7	26.4	94%
70273	A635	Manchester	40.4	37.8	32.5	21.7	37.1	16.1	94%
46068	A57M	Manchester	40.0	39.5	32.0	21.5	40.3	18.0	99%
56370	A57	Manchester	41.5	37.1	26.5	18.4	42.2	18.7	89%
36632	A62	Oldham	38.4	43.0	27.4	18.9	52.0	24.1	97%
36585	A57	Salford	38.7	48.4	26.5	18.4	69.8	30.0	125%
26352	A34	Stockport	40.3	44.6	20.5	14.7	64.2	29.9	111%
38735	A34	Stockport	40.6	41.6	20.5	14.7	57.0	26.9	103%
99618	A635	Tameside	42.2	47.4	26.9	18.5	66.5	28.9	112%
58022	A56	Trafford	38.5	38.2	16.8	12.3	54.0	25.9	99%

<sup>1</sup> BG = Background

- 3.1.3 Comparison of the model results for 2021 show reasonable agreement between the PCM links predicted to be in exceedance and local model total NO<sub>2</sub> concentrations for the majority of road links assessed. Of the 12 links identified, the local model concentrations are typically greater, but only two sites (38354: A58 in Bury and 36585: A57 in Salford) are greater than ±25%, and Bury is also the worst case location as identified in the local modelling. The local road network in the vicinity of these PCM links is complex so direct comparison is difficult. The Bury A58 concentration of 52.8 µg/m<sup>3</sup> is the maximum of any PCM receptor point on roads managed by local authorities.
- 3.1.4 The A635 in Tameside (Census ID:99618) has the highest PCM link concentration of 42.2 µg/m<sup>3</sup>, and is predicted to have a maximum concentration of 47.4 µg/m<sup>3</sup> in the detailed local modelling. Again, the local road network in the vicinity of this PCM link is complex so direct comparison between the models is difficult.
- 3.1.5 However, the local modelling also predicts exceedances at a number of additional PCM links across Greater Manchester in 2021. These include locations in districts that were not identified as non-compliant in the national modelling, i.e. Rochdale and Wigan. There are 160 stretches of local road (road links) or 203 modelled points, where concentrations of NO<sub>2</sub> are forecast to exceed 40 µg/m<sup>3</sup> for NO<sub>2</sub> beyond 2020, across GM as a whole. 137 of these local road links (or 146 modelled points) coincide with roads identified in the national PCM model. Typically, these roads have the greatest car use and heavy freight flows. The remaining 23 road link exceedances (or 57 modelled points) are on shorter stretches of local roads, primarily around town and city centres across Greater Manchester, which are not included in the national model but carry high volumes of traffic, including significant numbers of buses, taxis and Light Goods Vehicles (LGVs).
- 3.1.6 These results are summarised in the following section of this report, split by district. They are described based on the number of output points from the local network (rather the PCM network), and also include roads managed by the local authority excluded from the PCM network. The reporting does not include those roads managed by Highways England (HE) - which include motorways and trunk roads, although these roads and vehicle traffic are necessarily included in modelling process.

3.1.7 Table 2 and Chart 1 show the exceedances identified by local modelling and upon which the proposed GM CAP is based. Exceedances are found in the town and city centres and on major roads, particularly those close to the motorway network. The greatest cluster of sites in exceedance of the AQO is found in Manchester city centre, and this is also where some of the highest annual mean concentrations are predicted. This reflects higher traffic volumes, congestion, high buildings which create air pollution 'canyons', and high background levels of pollution. The aim of the GM CAP is to deliver measures that deliver compliance at these locations as soon as possible, without redistributing the problem to other locations. The geographical spread of NO<sub>2</sub> exceedances throughout Greater Manchester is shown in Chart 1 for 2021 and clearly highlights the complexity of the air quality issues the Clean Air Plan is trying to address. The modelled Do Minimum scenario NO<sub>2</sub> concentrations and exceedances for all of GM and then each district are presented separately in Figures 2 to 12 for 2021, Figures 13 to 23 for 2023, and Figures 24 to 34 for 2025.

**Chart 1: Predicted NO<sub>2</sub> Exceedances in Greater Manchester in the Local Modelling in 2021**

3.1.8 Table 2 shows the exceedances identified in the national modelling, using the PCM, and in the local modelling. The local modelling encompasses a wider road network than the PCM, including local and strategic roads. The primary spending objective of the GM CAP, as set out by JAQU, is to tackle exceedances identified by the local modelling on roads included within the PCM network.

**Table 2: Predicted NO<sub>2</sub> Exceedances in Greater Manchester in the PCM and Local Modelling in 2021**

Local authority	National (PCM) Model exceedances links	Local Model exceedances points on PCM links	Additional Local Model point exceedances on minor roads (non-PCM links)*	Total Local Model point exceedances
Bolton Metropolitan Borough Council	1	12	1	13
Bury Metropolitan Borough Council	1	12	4	16
Manchester City Council	3	55	21	76
Oldham Metropolitan Borough Council	0	9	0	9
Rochdale Metropolitan Borough Council	0	5	0	5
Salford City Council	1	34	2	36
Stockport Metropolitan Borough Council	2	16	5	21
Tameside Metropolitan Borough Council	1	13	0	13
Trafford Metropolitan Borough Council	1	2	5	7
Wigan Metropolitan Borough Council	0	2	5	7
<b>Total</b>	<b>10</b>	<b>160</b>	<b>43</b>	<b>203</b>

\*These are road links that are not included in the national PCM model but have been modelled locally.

- 3.1.9 Table 3 shows the distribution of non-compliant sites across Greater Manchester, both by spatial type and also in terms of how close they are to compliance. This shows that, whilst levels of NO<sub>2</sub> are below the AQO across much of the road network, in 2021 it is anticipated that 203 sites will remain non-compliant, of which 49 are predicted to experience annual mean concentrations between 45 µg/m<sup>3</sup> and 50 µg/m<sup>3</sup>, and 11 to experience annual mean concentrations over 50 µg/m<sup>3</sup> and as high as 57 µg/m<sup>3</sup>. A further 485 sites are compliant but experience annual mean concentrations close to the AQO and given modelling uncertainties, could be at risk of still exceeding in 2021.
- 3.1.10 Chart 1, Table 2 and Table 3, demonstrate the spatial diversity of predicted exceedances across GM, with predicted exceedances occurring both in urban centres, and close to heavily trafficked routes serving them (including those influenced by the motorway).
- 3.1.11 By 2023, the transition towards cleaner vehicles that would be expected without further action, as well as a reduction in background emissions, leads to a substantial reduction in the number of sites in exceedance of the AQO, from 203 in 2021 to 69 in 2023, and a reduction in the number of sites in compliance but close to the AQO from 485 in 2021 to 209 in 2023.
- 3.1.12 By 2025, the improvement in air quality expected without further action leads to a very substantial reduction in the number of sites in exceedance of the AQO, from 203 in 2021 to 12 in 2025, and a reduction in the number of sites in compliance but close to AQO from 485 in 2021 to 109 in 2025. Nevertheless, this suggests that achieving compliance with the AQO will take more than seven years in Greater Manchester without further action.
- 3.1.13 Information on air quality performance for individual local authorities can be found in appendices supporting the OBC Strategic Case.
- 3.1.14 It should be noted that forecasts of improvements in air quality have been shown to be overly optimistic in the past; if this was the case then compliance may take longer to achieve and any intervention would be of greater value than presented in this OBC.

**Table 3: Predicted annual mean NO<sub>2</sub> concentrations at points on the Greater Manchester road network - 2021, 2023 and 2025 without further action ('Do Minimum')**

Road classification <sup>2</sup>	Compliant sites		Non-compliant sites			
	Very compliant (below 35 µg/m <sup>3</sup> )	Compliant but marginal (35 to 40 µg/m <sup>3</sup> )	Non-compliant (>40 to 45 µg/m <sup>3</sup> )	Very non-compliant (>45 to 50 µg/m <sup>3</sup> )	Extremely non-compliant (>50 µg/m <sup>3</sup> )	Total non-compliant (>40 µg/m <sup>3</sup> )
<b>2021</b>						
Inside Manchester-Salford Inner Relief Route (IRR)	150	72	29	19	5	53
Other urban centres	170	48	14	5	0	19
Other locations	1531	365	100	25	6	131
<b>Total</b>	<b>1851</b>	<b>485</b>	<b>143</b>	<b>49</b>	<b>11</b>	<b>203</b>
<b>2023</b>						
Inside IRR	205	39	21	9	1	31
Other urban centres	213	20	4	0	0	4
Other locations	1869	150	30	4	0	34
<b>Total</b>	<b>2287</b>	<b>209</b>	<b>55</b>	<b>13</b>	<b>1</b>	<b>69</b>
<b>2025</b>						
Inside IRR	240	27	8	0	0	8
Other urban centres	233	4	0	0	0	0
Other locations	1990	78	4	0	0	4
<b>Total</b>	<b>2463</b>	<b>109</b>	<b>12</b>	<b>0</b>	<b>0</b>	<b>12</b>

*Note: The total number of predicted points and distribution of those points changes between 2021 and 2023/2025 due to planned changes to the road network.*

<sup>2</sup> "Inside Inner Relief Route" is the area encircled by the Inner Relief Route. "Other urban centres" are areas that met a definition used for the purposes of air quality modelling for Option 4 testing, but generally comprise the town centres of the relevant district. "Other locations" are roads outside of Urban centres and the Inner Relief Route.

- 3.1.15 Based on extrapolation from the available transport model years, Greater Manchester is predicted to become fully compliant with the AQO for NO<sub>2</sub> in 2027.
- 3.1.16 In order to deliver compliance, emissions reductions equivalent to reducing traffic emissions by as much as 40-50% are required at some locations. This proposed GM CAP has assessed solutions that aim to deliver equivalent reductions in emissions in the shortest possible time and without limiting the ability to travel around the region or preventing successful business operations.

#### **Comparison of Do Minimum Results with those used in the OBC**

- 3.1.17 There is a reduction in the number of points of exceedance in 2021 from those presented in the OBC from 250 to 203, primarily as many of the more marginal exceedances along ‘Other Locations’ have reduced. However, over time into 2025, the emissions along bus routes are more persistent due to an older modelled fleet mix, so there is an increase in overall exceedances in 2025 from 8 to 12.
- 3.1.18 There are predicted to be exceedances in all 10 districts in the Do Minimum scenarios for both 2021 and 2023. By 2025, exceedances are only predicted in Salford, Manchester and Bury, which is consistent with the OBC scenarios (following the model refinement to A62 Oldham).
- 3.1.19 The updated modelling shows results consistent with methodological modelling alterations described previously. The locations where car and van flows are greatest have a reduced number of exceedances, typically sites classed as ‘Other Locations’. Those sites in the IRR where bus contributions are most significant have an increased number of exceedances. The number of exceedances at sites classed as ‘Other Urban Centres’ are relatively unaltered, most likely because increases in bus emissions and reductions in car and van emissions offset one another.
- 3.1.20 Beyond the IRR, the key last points of exceedance in the OBC in 2025, which were on roads classed as ‘Other Locations’, still remain at:
  - A57 Regent Rd, Salford
  - A6 Ardwick Green, Manchester
  - A58 Bury Bridge, Bury
- 3.1.21 Additionally, there is an extra exceedance at:
  - A6 Chapel St, Salford.
- 3.1.22 The OBC exceedance site on the A56 Bury New Road, adjacent to M60 J18, is no longer predicted to exceed in 2025.

## **Influence of Highways England's Strategic Road Network**

- 3.1.23 While the maps and tables show a number of exceedances on local roads that are in close proximity to the Strategic Road Network (SRN), which is managed by Highways England (HE), it should be noted that the mapping and analysis does not include exceedances actually allocated to the SRN. This is because Highways England have not been required to act to reduce NO<sub>2</sub> under the same direction as local authorities. Nevertheless, at local roads close to the SRN, pollution caused by motorway traffic can be as much as 50% greater than that from the local road. Furthermore, there are properties in exceedance situated along the motorway where there is very little local road traffic and 100,000 vehicles passing per day on the SRN.
- 3.1.24 Highways England have eight links predicted to be non-compliant in the PCM network based on national modelling. Highways England is currently assessing sections of the SRN around Greater Manchester to explore potential Measures to reduce air quality impacts. The GM CAP is predicted to provide substantial improvements in air quality on the SRN in Greater Manchester as most of the traffic on that network enters or exits within the region, and is therefore in scope for the proposed CAP daily charges. The modelling outputs of PCM equivalence points on HE managed roads have been produced in the CAP modelling process, but it should be noted that these points may not be representative of exposure and have not been checked against the criteria for 'qualifying features' agreed between JAQU and HE. Therefore, use of these results for interpretation of compliance of the SRN with the AQO is not appropriate.

## **Why is there a problem in Greater Manchester?**

- 3.1.25 As demonstrated by the scale of exceedances identified in the Government's PCM model and the local modelling, Greater Manchester suffers from some of the worst air quality in the UK. The reasons for this are complex and multi-faceted.
- 3.1.26 Vehicles travelling on the roads in Greater Manchester traffic are older and more polluting than the national average, and traffic speeds are slower than average. This means the options considered in Greater Manchester may need to be bolder.

- 3.1.27 The transport modelling has also been analysed to understand the origins and destinations of traffic, by vehicle type, on these links. This shows that whilst a large proportion of traffic is associated with accessing the urban centres, there is also a significant use of the local road network to access the motorway for trips spread around Greater Manchester and beyond. The analysis indicates that a range of measures will be necessary to tackle Greater Manchester's NO<sub>2</sub> concentrations due to the diverse spatial context and reasons for travel.
- 3.1.28 Vehicle travel in Greater Manchester has been changing over the past 20 years. Traffic volumes on Highways England controlled motorways have been increasing but elsewhere on the local road network traffic levels have been stable or falling.
- 3.1.29 Analysis of the pollution sources at each location of exceedance has been undertaken, and an estimate of the emissions reduction required from vehicle transport has been calculated to enable compliance with the AQO for NO<sub>2</sub>. This was utilised to inform the detail of measures required by the GM CAP.
- 3.1.30 The analysis shows that there are very diverse factors affecting vehicle emissions across Greater Manchester, with vehicle types and levels often differing between roads in close proximity to each other (see Chart 2). In many locations where there are significant exceedances, such as on roads in a city/town centre, the road network performs a variety of complex transport functions and therefore carries a diverse range of traffic, including cars, vans, Heavy Goods Vehicles (HGVs), buses and taxis.
- 3.1.31 The success of any potential scheme is determined by the removal of all predicted exceedances in the shortest possible time. The transport and emissions modelling process was developed based on the published JAQU guidance, and a range of indicative early schemes were tested to understand the likely scale of impact on NO<sub>2</sub> of charging CAZ schemes in 2021. This determined that compliance was not feasible in 2021, and therefore additional transport models were also constructed for 2023 and 2025 to understand the trajectory of NO<sub>2</sub> concentrations into the future.
- 3.1.32 To describe how the Consultation Option delivers compliance across GM, the results for a subset of the modelled receptors have been summarised. Chart 2 shows 16 of the key points that would eventually come to define compliance within GM and each district. These sites have been selected based on the maximum predicted concentrations i.e. last points of compliance in each district in the Consultation Option, plus where there are several points with high concentrations, those which display notably different source apportionment by vehicle type were added.

- 3.1.33 The air quality data and emissions source apportionment is provided in Table 4 for 2023, the year of full scheme opening. This table shows how each vehicle type contributes to the total road transport emissions on a given road link, and how variable they are across GM.
- 3.1.34 For example, buses are an insignificant fraction on the links in Bolton and several of the other districts, whilst on the links close to the IRR in Manchester and Salford, bus emissions account for 51-79% of total transport emissions in this subset of sites.
- 3.1.35 Emissions from freight vehicles (HGVs & LGVs) are often over 50% of emissions, with nine of the 16 sites having goods vehicle emissions >46%. Cars form a more consistently substantial proportion of total emissions, but also comprise the vast majority of vehicle movements, usually >75%.
- 3.1.36 Full data for all modelled links, years and scenarios is presented in Appendix B.

## **4 CAP Consultation Option**

- 4.1.1 As previously described, local modelling has revealed the problem to be larger than that initially identified by Government. Local modelling predicts a greater spatial distribution of NO<sub>2</sub> exceedances across roads in Greater Manchester and generally higher concentrations of NO<sub>2</sub> in specific locations.
- 4.1.2 Given the spatially variable and complex causes of exceedances across Greater Manchester, and with each exceedance site differing, the scale of the challenge means that the solutions are inter-related. Localised solutions such as re-routing traffic or tackling local pinch points will clearly be insufficient to tackle the region-wide problem, and risk simply moving the problem elsewhere.
- 4.1.3 A series of options, containing packages of Measures including CAZ schemes of different categories and sizes, were developed in response to the problem identified by local modelling and assessed for the OBC, with a preferred option selected. Further details of the options and modelling can be found in the OBC Strategic Case and associated technical T1/2/3/4 and AQ1/2/3 documents.
- 4.1.4 Since the OBC further work has been undertaken to refine and improve the modelling process for this preferred option, to meet the Government's technical requirements the Ministerial Direction. This is set out in T4 and in a series of supporting Technical Notes.
- 4.1.5 The CAP option which is being taken forward for consultation includes the following measures:
  - A category C CAZ covering the whole of Greater Manchester in 2021, with temporary exemptions to 2023 for LGVs, minibuses, GM-licensed wheelchair accessible hackney cabs and private hire vehicles, and GM-registered coaches;
  - Measures to promote sustainable journeys and invest in electric vehicle charging infrastructure for taxis and a try-before-you-buy electric taxi scheme;
  - Funds to upgrade the bus fleet;
  - Funds for Taxi, PHV, LGV and HGV operators to upgrade their vehicles, plus Loan/Finance measures.

## **5 Summary Results for the Consultation Option**

5.1.1 Table 5 shows the number of sites remaining in exceedance of legal limits in 2021, 2023, 2024 (based on linear interpolation of 2023 and 2025 point specific results) and 2025 under the Do Minimum scenario and with the Consultation Option by local authority. The results show:

- without action, there are predicted to be 203 non-compliant sites across Greater Manchester in 2021, 69 in 2023 and 12 remaining in 2025, with compliance forecast to be achieved by 2027;
- with action, two authorities (Wigan and Trafford) are forecast to become compliant in 2021, with 57 points of non-compliance remaining across the rest of the region;
- with action, by 2023 eight authorities are forecast to be compliant, with three non-compliant sites remaining in Manchester and Bury; and
- with action, GM achieves compliance in 2024, by removal of the last 12 exceedances.

**Table 5: Number of sites remaining in exceedance of legal limits for NO<sub>2</sub> concentrations by year, Greater Manchester, by local authority for the range of modelled options**

	2021		2023		2024 (interpolated)		2025	
	Do Min.	Consult. Option	Do Min.	Consult. Option	Do Min	Consult. Option	Do Min.	Consult. Option

<b>GM Total</b>	<b>203</b>	<b>57</b>	<b>69</b>	<b>3</b>	<b>31</b>	<b>0</b>	<b>12</b>	<b>0</b>

*Note: Calculation of 2024 was undertaken using linear interpolation between the 2023 and 2025 modelled NO<sub>2</sub> results for each model output point.*

5.1.2 Greater Manchester aims to deliver compliance in the shortest possible time in a way that takes into account the need to minimise human exposure. Table 6 demonstrates the benefits being delivered in each year in terms of reduced concentrations even at sites remaining in exceedance in that year. This also shows that the number of sites close to exceedance reduces considerably in each year as a result of the Plan. Health benefits continue to be delivered by reductions in NO<sub>2</sub> concentrations even below the AQOs. In particular:

- With action, there are no sites that are extremely non-compliant (with concentrations over 50 µg/m<sup>3</sup>) in the first year; and substantial reduction in the number that are very non-compliant (with concentrations between 45-50 µg/m<sup>3</sup>) in the same year.
- By 2023, all sites are at, or close to, compliance across Greater Manchester. Three sites are predicted to remain non-compliant two in Manchester and one in Bury, but in all cases the predicted concentrations are close to 40 µg/m<sup>3</sup>.
- With action, compliance is achieved in all local authorities across Greater Manchester by 2024. With the vast majority of sites across the region predicted to have concentrations less than 35 µg/m<sup>3</sup>.

**Table 6: Number of modelled sites by scale of NO<sub>2</sub> exceedance by year, Greater Manchester**

Scenario	Compliant sites		Non-compliant sites				NO <sub>2</sub> Change (µg/m <sup>3</sup> )
	Very compliant (below 35 µg/m <sup>3</sup> )	Compliant but close (35 to 40 µg/m <sup>3</sup> )	Non-compliant (40 to 45 µg/m <sup>3</sup> )	Very non-compliant (45 to 50 µg/m <sup>3</sup> )	Extremely non-compliant (> 50 µg/m <sup>3</sup> )	Total non-compliant (> 40 µg/m <sup>3</sup> )	
<b>2021</b>							
Do minimum	1851	485	143	49	11	<b>203</b>	na
Consult. Option	2266	216	52	5	0	<b>57</b>	-146
<b>2023</b>							
Do minimum	2287	209	55	13	1	<b>69</b>	na
Consult. Option	2485	51	3	0	0	<b>3</b>	-66
<b>2025</b>							
Do minimum	2463	109	12	0	0	<b>12</b>	na
Consult. Option	2525	14	0	0	0	<b>0</b>	-12

5.1.3 Table 7 shows the concentrations at the highest point of exceedance with each scenario in each year. This shows that, by 2023, the highest exceedances in the Consultation Option below 42 µg/m<sup>3</sup>, whereas in the Do Minimum the highest exceedance is nearly 51 µg/m<sup>3</sup>.

**Table 7: Maximum NO<sub>2</sub> concentration as forecast in each year, in µg/m<sup>3</sup>**

Scenario	2021	2023	2025
Do Minimum	56.9	50.8	45.4
Consult. Option	48.2	41.5	39.3

#### **Detailed Discussion of Transport and Air Quality Impacts for the Consultation Option**

- 5.1.4 The impacts of the proposed option will be discussed further with reference to the key exceedance points identified earlier, examining details on the changes to traffic and emissions by vehicle type.
- 5.1.5 The air quality and source apportionment data for the Consultation Option in 2023 are provided in Table 8, whilst the impacts on the traffic flows are provided in Table 9.

- 5.1.6 With the Consultation Option in effect, there are predicted to be three exceedances remaining in 2023, two located inside the Manchester regional centre and one in Bury. Both are only marginally above the AQO with the option, and are predicted to be compliant in 2024.
- 5.1.7 Of the Manchester regional centre sites which are still non-compliant, both are on adjacent sections of the A34, either side of Deansgate. These are the A34 John Dalton St (1268\_1269) which has the highest concentration at 41.5 ug/m<sup>3</sup>, and the A34 Bridge St (1268\_46301) at 41.1 ug/m<sup>3</sup>.
- 5.1.8 The A34 John Dalton St experiences a reduction of -9.3 ug/m<sup>3</sup> due to the proposed option, whilst A34 Bridge St reduces by -7.9 ug/m<sup>3</sup>. Both of these sites have very similar source apportionment with emissions dominated by buses. Of the total change in emissions due to the option at John Dalton St, 92% of this NOx reduction is related to the bus fleet, with a further 3% from both HGVs and LGVs.
- 5.1.9 The other remaining non-compliant site at A58 Bury Bridge (2237\_3790\_DW) experiences a reduction of 6.0 ug/m<sup>3</sup>, resulting in a concentration of 40.9 ug/m<sup>3</sup>. Here, NOx emissions are distributed across all vehicle types, with 43% from freight vehicles and 16% from buses in the Do Minimum. Of the total change in emissions due to the option, 42% of this NOx reduction is related to the bus fleet. Additionally 27% of the NOx reduction came from HGVs upgrading to become compliant (300 veh/day), and 26% from LGVs upgrading to become compliant (3,300 veh/day).
- 5.1.10 The A6 Ardwick Green (3056\_3842\_DW) experiences the greatest improvement, reducing by -9.7 ug/m<sup>3</sup> due to the option, which is located just outside of the IRR . Of the total change in emissions due to the option, 50% of this NOx reduction is related to the bus fleet, with a further 21% (100 veh/day) and 19% (1,750 veh/day) from HGVs and LGVs, respectively.
- 5.1.11 All sites experience significant reductions in NO<sub>2</sub> concentrations due to the proposed option. The A57 (1349\_2993\_DW) in Salford becomes narrowly compliant, with a reduction of -5.4 ug/m<sup>3</sup>. Of the total change in emissions due to the option, 54% of this NOx reduction came from HGVs upgrading to become compliant (450 veh/day), and 33% from LGVs upgrading to become compliant (2,700 veh/day). There are very few buses on this section of road.

- 5.1.12 In addition to the subset of sites selected for narrative discussion, there are certain links located on key bus corridors, including sections of the A34, A6, A56, A5103 and A62 located within the IRR where bus emissions form over 90% of the total emissions in the Do Minimum scenario. These corridors typically have very poor air quality with Do Minimum concentrations above 45 ug/m<sup>3</sup> in 2023. At these sites the consultation option, which leads to a fully Euro VI bus fleet, is highly effective in reducing NO<sub>2</sub> concentrations typically by between -10 to -15 ug/m<sup>3</sup>. As a result these locations do not comprise the last points of compliance for GM with the option in place, but still represent significant improvements to air pollution in GM.
- 5.1.13 It should be noted, that the number of AADT flows responding as upgrading, is not directly comparable to the total number of unique vehicles affected, as some vehicles are likely to travel along the link more than once per day (e.g a return trip) or on multiple links along overall routes (e.g. through Salford into Manchester regional centre).
- 5.1.14 There is also the likely effect that some vehicles have been reassigned onto these key routes from equivalent 'rat-running' routes, due to slight reductions in overall demand (and modelled trip delays or 'congestion') hence the gap between the reduced non-compliant flows and increased compliant flows, particularly for cars and LGVs, is relatively small.
- 5.1.15 The modelled Consultation Option scenario NO<sub>2</sub> concentrations and exceedances for each district are presented separately in Figures 34 to 44 for 2021, Figures 45 to 55 for 2023, and Figure 56 for 2025. Full results for all modelled receptors in exceedance in the Do Minimum scenario for 2021 are presented in Appendix B.

## Conclusions

- 5.1.16 There have been a number of best practice updates to assumptions used in the prediction of future year traffic and emissions forecasts applied since the assessment of the OBC. Comparison of the NO<sub>2</sub> model results for 2021 continue to show reasonable agreement between the national PCM model and local model concentrations, at the links predicted to be in exceedance for by national PCM modelling. Again, the local modelling identified a larger number of locations which are expected to exceed the AQO, and higher concentrations of NO<sub>2</sub> in specific locations. Local modelling has shown that all ten local authorities contain locations expected to be in exceedance of the AQO for annual mean NO<sub>2</sub> after 2020. This reflects that local modelling uses more detailed sources of data and more refined analytical tools.
- 5.1.17 Whilst levels of NO<sub>2</sub> are below the AQO across much of the road network, in 2021 it is anticipated that 203 sites will remain non-compliant, of which 49 are predicted to experience annual mean concentrations between 45 µg/m<sup>3</sup> and 50 µg/m<sup>3</sup>, and 11 to experience annual mean concentrations over 50 µg/m<sup>3</sup>, with a maximum of 57 µg/m<sup>3</sup>. By 2023, the transition towards cleaner vehicles that would be expected without further action, as well as a reduction in background concentrations, leads to a substantial reduction in the number of sites in exceedance of the AQO, from 230 in 2021 to 69 in 2023. The highest and longest lasting exceedances are predicted in central Manchester, but exceedances occur throughout Greater Manchester.
- 5.1.18 The air quality modelling indicates that compliance in GM with the NO<sub>2</sub> AQO is predicted to occur without a CAP intervention by 2027.
- 5.1.19 The analysis shows that there are very diverse factors affecting vehicle emissions across Greater Manchester, with vehicle types and levels often differing between roads in close proximity to each other. In many locations where there are significant exceedances, such as on roads in a city/town centre, the road network performs a variety of complex transport functions and therefore carries a diverse range of traffic, including cars, vans, Heavy Goods Vehicles (HGVs), buses and taxis.
- 5.1.20 A series of options, containing packages of Measures including CAZ schemes of different categories and sizes, were developed in response to the modelled and measured exceedances for the OBC, with a preferred option selected. This option has been further refined, with full modelling and assessment carried out across three model forecast year scenarios, and reported herein.
- 5.1.21 The preferred option has been further developed to ensure compliance by 2024, as required by the Ministerial Direction and consistent with the preferred option from the OBC.
- 5.1.22 By 2023, only three sites are predicted to remain non-compliant, with two located in the regional centre of Manchester and the other in Bury.

- 5.1.23 The consultation option would deliver significant reductions in modelled NO<sub>2</sub> concentrations at all areas of poor air quality across GM. At the last remaining points of compliance, this is predicted to be -9.7 ug/m<sup>3</sup> in 2023 in Manchester and -6.0 ug/m<sup>3</sup> in Bury. At certain key bus corridors inside the IRR, there are predicted to be improvements in NO<sub>2</sub> concentration of upto -15 ug/m<sup>3</sup>.
- 5.1.24 A wide range of sensitivity tests and analyses were undertaken for the OBC phase, based on guidance issued by JAQU. These indicated that the modelled concentrations could be over- or under-estimated, however this is unavoidable and a reasonable aspect of any predictive analysis. Overall, it was concluded that there are a variety of assumptions that could act in combination either synergistically or antagonistically, to mean that future concentrations are higher or lower, and that the impacts of the scheme could be greater or lesser, than those predicted using the selected methodology in the OBC. However, the process applied was considered to be reasonable and appropriate, and the conclusions regarding the case for the scheme are robust. These sensitivity tests have not been updated at this stage of the process, but are expected to be for submission of the FBC.
- 5.1.25 Further refinement of the modelling may be necessary depending on the outcomes of any consultation, for example in relation to the impact of potential charge levels, funds or discounts and exemptions.

## **Appendix A – Air Quality Model Verification**

- 6.1.1 A total of 314 monitoring sites were reviewed for the model verification process and of these a number of sites were discounted for a variety of reasons including low data capture, inappropriate location (e.g. bus stop), unidentified location, or co-location with a continuous analyser site. There were 194 sites used for the model verification, 147 for roadside predictions and 47 for background mapping adjustment. The monitoring data for all sites is provided in the files issued to JAQU with the AQ3 document. These files contain the model verification performance by site, including background concentrations and verification zone. Sites which were excluded from the verification process are detailed in Table 15.
- 6.1.2 Initially, the Defra background maps were compared with background monitoring sites. Of those sites reported as background type locations by the local authorities, only those sites with very low modelled road component NOx were used in the verification process. These monitoring sites were grouped as ‘Zone 2’, and the Defra background maps were found to under-estimate the measured Total NOx and Total NO<sub>2</sub> concentrations by a factor of 1.30. The background NOx and NO<sub>2</sub> maps were therefore uplifted by this adjustment factor, and used in the modelling process.
- 6.1.3 There are 16 continuous analyser sites in GM, of which nine were suitable for roadside verification and four for background verification. Three are background sites, but with a road component which meant they were not considered suitable for either grouping. Where the diffusion tube data was used for verification, road NOx was back calculated using the Defra NOx to NO<sub>2</sub> calculator v6.1, with calculated f-NO<sub>2</sub> from the dispersion modelling input for each site.
- 6.1.4 The air quality modelling outputs were converted to NO<sub>2</sub> and then compared to the monitoring data. Only monitoring sites with data capture greater than 75% in the calendar year 2016 were used in the verification process.
- 6.1.5 The initial modelling applied the canyon module to the entire GM modelled road network. The results were then reviewed spatially for patterns of model performance, and each site checked locally. The canyon model input files were produced by CERC on behalf of TfGM. These initial model outputs were reviewed, and it was considered that the canyon module was performing poorly in areas which were not significantly built up, potentially due the relatively longer length of less homogenous road links, and additionally compromising model run times over the very large study area.

- 6.1.6 A zonal approach to model verification was considered necessary, to refine the spatial performance of the model, including application of the canyon module. The study area was split into three zones:
- the area of central Manchester inside the Inner Relief Road (IRR) where there is a predominance of tall buildings (Zone 5),
  - the A57 Hyde Road at Mottram (which is operated by Highways England) which is very narrow and congested (Zone 4); and
  - the remainder of GM (Zone 1).
- 6.1.7 The canyon module was used in Zone 4 and 5, but not in Zone 1. A total of 118 sites were used in the verification process for Zone 1 (remainder of GM outside the Manchester city centre Inner Ring Road). Twenty one sites were included for Zone 4 (A57 Mottram) and eight sites were included for Zone 5 (sites within the Manchester-Salford Inner Relief Road). These sites are presented in Figure 1.
- 6.1.8 The results for all monitoring sites prior to adjustment (but with the canyon module applied in Zone 4 and 5 locations) are presented in Table 10. These show that the study area showed a slight systematic bias of under prediction (fractional bias of 0.27) with an RMSE of 12.5  $\mu\text{g}/\text{m}^3$ . Analysis was undertaken to address the overall under prediction, and refine the model performance.
- 6.1.9 The verification process was applied following guidance in LAQM.TG(16) to adjust Road NO<sub>x</sub>, with a further adjustment applied to Road NO<sub>2</sub>, and the resulting model performance for the three zones considered are presented in Table 10.

**Table 10: Modelled verification results for roadside locations**

Annual mean conc. bands ( $\mu\text{g}/\text{m}^3$ )	No adjustm't: All roadside sites	No adjustm't: Zone 1	Zone 1	No adjustm't: Zone 4	Zone 4	No adjustm't: Zone 5	Zone 5
No. sites	147	118	118	21	21	8	8
Mod NO <sub>x</sub> Rd v Mon NO <sub>x</sub> Rd Factor	n/a	n/a	1.98	n/a	2.003	n/a	1.494
Mod NO <sub>2</sub> Rd v Mon NO <sub>2</sub> Rd Factor	n/a	n/a	1.002	n/a	0.981	n/a	0.936
RMSE	12.5	10.9	8.3	20.0	12.1	8.5	7.0
Fractional Bias	0.27	0.26	0.07	0.39	0.03	0.12	0.02
Correlation Coefficient	0.68	0.55	0.52	0.70	0.70	0.80	0.78
No. sites within $\pm 25\%$	78	64	94	7	17	7	7

*Note: Zone 2 was used for background verification and Zone 3 was not used.*

- 6.1.10 The results show that the RMSE is improved and the fractional bias reduced compared to the overall dataset for each of the three zones. The number of sites within  $\pm 25\%$  of monitored concentrations in each zone is improved or remains the same. Each outlier site was reviewed to determine whether it should be excluded, but it was considered these should remain to describe the spread of the data. These verification factors were applied to the model results.
- 6.1.11 The model performance at each monitoring site is provided below by verification zone in Table 12 to Table 14, and the modelled road NO<sub>x</sub> and total NO<sub>2</sub> (pre- and post- adjustment) are provided for each zone in Graph 1 to 9.

- 6.1.12 The continuous analysers were highly variable in their response, possibly relating to variations in f-NO<sub>2</sub>, amongst other factors. Therefore, the performance of continuous analysers was also considered separately to diffusion tubes. A separate approach, using just the continuous analyser data to produce the road NOx adjustment factor, and then both continuous analysers and diffusion tubes to produce the a total NO<sub>2</sub> adjustment factor was applied to Zone 1 (Zone 4 and 5 only contained one continuous analyser and this method was not considered appropriate). The model performance using this approach is summarised in Table 11.
- 6.1.13 Overall, the RMSE and number of outliers sites were poorer using this approach, whilst the Fractional Bias and Correlation Coefficient were slightly better. The test was not considered to significantly improve overall model performance, and therefore this approach has not been applied. This is discussed further in the sensitivity analysis in Appendix C.

**Table 11: Modelled verification results for roadside locations – Continuous Analyser for NOx Rd Adjustment Test**
